

REDUCING STICTION IN A MEMS DEVICE WITH AN APPLIED FORCE

ABSTRACT OF THE DISCLOSURE

5 A method is disclosed for operating a MEMS device having a flap
that is movable with respect to a base. The method includes
applying a force to the flap to move the flap at least
partially out of contact with an underlying base. Means for
applying such a biasing force may be incorporated into a
10 microelectromechanical (MEMS) apparatus having a base and a
flap with a portion coupled to the base so that the flap may
move out of the plane of the base between first and second
position. The base may have a cavity with largely vertical
sidewalls that contact a portion of the flap when the flap is
15 in the second position. Electrodes may be placed on the vertical
sidewalls and electrically isolated from the base to provide
electrostatic clamping of the flap to the sidewall. The base
may be made from a substrate portion of a silicon-on-insulator
(SOI) wafer and the flap defined from a device layer of the SOI
20 wafer. The flap may be connected to the base by one or more
flexures such as torsional beams. An array of one or more of
such structures may be used to form an optical switch.
